Greenhouse gas emissions - data -

How did we get into trouble

Global greenhouse gas emissions by sector 2020

Global greenhouse gas emissions by sector

This is shown for the year 2016 – global greenhouse gas emissions were 49.4 billion tonnes CO₂eq.

Greenhouse gas emissions by agriculture

Food: greenhouse gas emissions across the supply chain

Greenhouse gas emissions¹ are measured in carbon dioxide-equivalents (CO₂eq)² per kilogram of food.

1. Greenhouse gas emissions: A greenhouse gas (GHG) is a gas that causes the atmosphere to warm by absorbing and emitting radiant energy. Greenhouse gases absorb radiation that is radiated by Earth, preventing this heat from escaping to space. Carbon dioxide (CO₂) is the most well-known greenhouse gas, but there are others including methane, nitrous oxide, and in fact, water vapor. Human-made emissions of greenhouse gases from fossil fuels, industry, and agriculture are the leading cause of global climate change. Greenhouse gas emissions measure the total amount of all greenhouse gases that are emitted. These are often quantified in carbon dioxide-equivalents (CO₂eq) which take account of the amount of warming that each molecule of different gases creates.

2. Carbon dioxide-equivalents (CO₂eq): Carbon dioxide is the most important greenhouse gas, but not the only one. To capture all greenhouse gas emissions, researchers express them in 'carbon dioxide-equivalents' (CO₂eq). This takes all greenhouse gases into account, not just CO₂. To express all greenhouse gases in carbon dioxide-equivalents (CO₂eq), each one is weighted by its global warming potential (GWP) value. GWP measures the amount of warming a gas creates compared to CO₂. CO₂ is given a GWP value of one. If a gas had a GWP of 10 then one kilogram of that gas would generate ten times the warming effect as one kilogram of CO₂. Carbon dioxide-equivalents are calculated for each gas by multiplying the mass of emissions of a specific greenhouse gas by its GWP factor. This warming can be stated over different timescales. To calculate CO₂eq over 100 years, we'd multiply each gas by its GWP over a 100-year timescale (GWP100). Total greenhouse gas emissions – measured in CO₂eq – are then calculated by summing each gas' CO₂eq value.

EU greenhouse gas emissions by agriculture

Agriculture accounts for 10% of the EU's greenhouse-gas emissions.

-24% From 1990 to 2012, greenhouse-gas emissions from agriculture in the EU decreased by 24%.

In southern Europe extreme heat events and reduced precipitation and water availability are expected to reduce crop yields, while the suitability for growing crops may improve in northern Europe.

Greenhouse-gas emissions from agriculture can be reduced further by:

- Better integration of innovative techniques
- Greater efficiency in meat and dairy production
- Capturing methane from manure
- Reducing food waste
- More efficient use of fertilisers
- Consuming less meat and other products with high carbon footprint

Globally

+14% Between 2001 and 2011, greenhouse-gas emissions from crop and livestock production grew by 14%.

+70% The demand for food is expected to grow by up to 70% in coming decades.

Did you know?

Meat and dairy products have the highest global footprint of carbon, raw materials and water per kilogramme of any food.

Post-farm transport and processing account for only a tiny fraction of the emissions linked to food.
